

# Secure Coding

# Overview

- ◆ Cybersecurity has risen to the top priority discussion items, and it is the subject of the US-Russia presidential communications. The number of ransomware attacks doubled in the past year, and other attacks are on the rise.
- ◆ This course teaches a comprehensive approach to cybersecurity. It starts with threat modeling, creating the lay of the land. It then continues with common attacks, with the principles of designing secure multi-layer systems, and goes into the details of secure coding for the target languages.
- ◆ Also included are securing runtime environments and modern security frameworks.

# Audience

- ◆ Developers, team leads, project managers

# Skill Level

- ◆ Introductory - Intermediate

# Duration

- ◆ Three days

# Format

- ◆ Lectures and hands on labs. (50% - 50%)

# Prerequisites

- ◆ Recommended: Cybersecurity awareness
- ◆ Comfortable developing code in the target environment

# Lab environment

- ◆ Zero Install: There is no need to install software on students' machines!
- ◆ A lab environment in the cloud will be provided for students.

# Students will need the following

- ◆ A reasonably modern laptop with unrestricted connection to the Internet. Laptops with overly restrictive VPNs or firewalls may not work properly.
  - A checklist to verify connectivity will be provided
- ◆ Chrome browser

# Detailed outline

# Threat modeling

- ◆ STRIDE attack classification
- ◆ Security terminology
- ◆ Threat modeling
- ◆ CVSS attack assessment
- ◆ Labs on threat modeling

# Common attacks

- ◆ Cross site scripting
- ◆ Malicious file execution
- ◆ Session hijacking
- ◆ Encryption
- ◆ Unsecured direct object reference
- ◆ Failure to authorize/hidden URLs
- ◆ Cross site request forgery (CSRF)

# Secure design

- ◆ Security at high level, all the way from testing, deployment, and maintenance
  - Start from non-functional requirements
- ◆ Layered design concepts
- ◆ Object layer
- ◆ Persistence layer
- ◆ Presentation layer

# Countermeasures

- ◆ Validation
- ◆ Validation controls
- ◆ Strong typing
- ◆ Regular expressions
- ◆ White list
- ◆ Scrubbing
- ◆ Black list
- ◆ Encoding
- ◆ CAPTCHA
- ◆ Honey pots
- ◆ Avoiding SQL injection
- ◆ Parametrizing queries/Prepared statements
- ◆ Stored procedures
- ◆ Entity Frameworks/Hibernate
- ◆ Avoiding cross site request forgeries

# Modern security frameworks

- ◆ Introduction to modern frameworks
  - Vault
  - Consul
  - Anthos
- ◆ Modern security design patterns
  - Dynamic secrets
  - Automatic credential rotation
  - Cubbyhole response wrapping
  - Encryption as a service
- ◆ Where to go from here

# Authorization and Authentication

- ◆ SSO (at least high-level)
- ◆ Spring security
- ◆ .NET authentication (just mention)
- ◆ Basic & Digest
- ◆ Forms
- ◆ Windows authentication (just mention)
- ◆ JAAS and other Java authentication services
- ◆ Authorization
- ◆ Password security
- ◆ Brute force attacks
- ◆ Password resets
- ◆ Secret questions/answers
- ◆ SSL/TLS

# Session security

- ◆ Perfect Secrecy
- ◆ Asymmetric and symmetric encryption
- ◆ Session IDs
- ◆ Policies
- ◆ Hijacking/Fixation Attacks

# Framework architecture

- ◆ Threading
- ◆ Privileges
- ◆ Audits/Logs
- ◆ Secure coding
- ◆ Encryption services
- ◆ Static code analysis
- ◆ Securing the API (both publishing and consuming API)
- ◆ JWT
- ◆ Dynamic code analysis (e.g. with Spotbugs)

# Securing the runtime environment

- ◆ Spring boot
- ◆ .NET (mention)
- ◆ Code Access
- ◆ GAC
- ◆ Strong named assemblies
- ◆ CLR
- ◆ Security Zones
- ◆ Permissions
- ◆ Security policy

# Security future

- ◆ Zero-trust networks
- ◆ Artificial intelligence
- ◆ Quantum computing / cryptography
